Abstract

The economic disruption triggered by the COVID-19 pandemic exposed the limits of conventional financial planning. Annual budgets built on single-point forecasts became obsolete within weeks, revenue in entire sectors fell abruptly, and firms that had optimised their balance sheets for efficiency rather than flexibility found themselves short of liquidity. This paper develops a conceptual framework, termed the Strategic Financial Modeling for Business Resilience (SFM-BR) framework, that integrates risk assessment, scenario planning and financial sustainability analysis into a single, iterative decision architecture. Drawing on an integrative review of literature in corporate finance, strategic management, risk management and organisational resilience, the framework is organised in five layers: (1) environmental sensing and risk identification, (2) risk assessment and quantification, (3) scenario planning, (4) strategic response and resource allocation, and (5) financial sustainability, all enclosed within a governance and continuous re-forecasting loop. The paper grounds the framework in dynamic capabilities, real options, contingency and resource-based theories, derives six testable propositions, and illustrates its application with a stylised numerical case of a mid-sized manufacturing firm facing four recovery archetypes (V, U, W and L). The illustration shows that liquidity adequacy and covenant compliance can diverge sharply across scenarios, and that pre-defined trigger-based responses materially improve survival odds under severe outcomes. The paper contributes a structured, theory-informed bridge between quantitative financial modeling and strategic resilience, and offers practical guidance for managers, boards, lenders and policymakers operating under deep uncertainty.

Keywords: Financial modeling; Business resilience; Scenario planning; Risk assessment; Liquidity management; Financial sustainability; Stress testing; Real options.

1. INTRODUCTION

1.1 Background

The year 2020 will be remembered as one of the most severe and synchronised economic disruptions of the modern era. Within the first quarter, public health measures introduced to contain the spread of

COVID-19 halted travel, closed retail outlets and factories, and fractured global supply chains. In April 2020 the International Monetary Fund projected a contraction of 3.0 percent in global output for the year, a forecast it subsequently revised downward to 4.9 percent in June before a partial upward revision in October (IMF, 2020a, 2020b). In the same month, the front-month West Texas Intermediate crude oil futures contract settled below zero for the first time in history, an event with severe consequences for commodity-exporting economies and for firms whose cash flows were linked to energy prices. Measures of economic uncertainty reached levels without precedent in the post-war period (Baker, Bloom, Davis, & Terry, 2020).

For individual businesses, the shock arrived through several channels at once. Demand collapsed in hospitality, aviation, non-essential retail and entertainment; supply disruptions affected manufacturers dependent on international inputs (Ivanov, 2020); receivables lengthened as customers conserved cash; and access to external finance tightened before central bank and fiscal interventions restored some stability. Survey evidence on small firms in the United States showed that many held cash sufficient to cover only a few weeks of expenses (Bartik et al., 2020). Evidence from listed companies indicated that firms entering the crisis with greater financial flexibility, more cash and lower leverage experienced smaller declines in market value (Fahlenbrach, Rageth, & Stulz, 2020; Ramelli & Wagner, 2020; Ding, Levine, Lin, & Xie, 2020).

These events placed financial modeling, a discipline often regarded as a technical support function, at the centre of strategic decision-making. Boards asked how long the organisation could survive under prolonged revenue loss, which costs could be adjusted and how quickly, whether lending covenants would hold, and which investments should be paused or accelerated. Answering such questions requires models that are forward-looking, driver-based, capable of representing multiple futures and connected to explicit management actions. Many organisations discovered that their existing planning tools, typically annual budgets with limited scenario capability, were not designed for this purpose.

Applied studies from emerging economies reinforced this picture. Financial institutions that had tested business continuity and disaster recovery plans adapted more smoothly to remote operations and branch closures (Fadero et al., 2020), while small multi-branch firms had to balance the cost of hybrid remote and on-site support arrangements against operational continuity (Anyanwu, 2020). Continuous-process plants and essential energy suppliers kept operating only by redesigning staffing, shift rotation and procurement arrangements around the pandemic (Babayemi et al., 2020; Uwagboe et al., 2020). In health

systems, the crisis tested emergency preparedness, diagnostic access and laboratory surveillance capacity (Abdulrazaq et al., 2019; Aminu-Ibrahim et al., 2020; Peteranaba et al., 2020; Yusuf & Abdulrazaq, 2018; Yusuf et al., 2020), and movement restrictions altered essential travel and consumption patterns in large African cities (Ajayi et al., 2020). Across these settings, the common lesson was that operational continuity depended on the ability to anticipate financial consequences and act on them quickly.

1.2 Problem Statement and Research Gap

Although each of the relevant building blocks is well established, they have developed in largely separate literatures. Corporate finance has examined liquidity, cash holdings and financial constraints (Opler, Pinkowitz, Stulz, & Williamson, 1999; Campello, Graham, & Harvey, 2010). Strategic management has developed scenario planning as a means of thinking about uncertain futures (Wack, 1985; Schoemaker, 1995). Risk management has produced quantitative tools such as Value at Risk, Cash Flow at Risk and stress testing (Jorion, 2007; Borio, Drehmann, & Tsatsaronis, 2014), alongside enterprise risk management (ERM) standards (COSO, 2017; ISO, 2018). Organisational resilience research has theorised how firms anticipate, absorb and recover from adversity (Linnenluecke, 2017; Williams, Gruber, Sutcliffe, Shepherd, & Zhao, 2017).

What remains underdeveloped is an integrated conceptual framework explaining how these elements should be combined into a coherent modeling architecture that supports strategic decisions during systemic disruptions. Scenario planning is frequently qualitative and disconnected from financial statements; quantitative risk tools are often confined to treasury or regulated financial institutions; and resilience research has seldom specified the financial mechanisms through which resilience is built and measured. The consequence is a gap between the narratives that executives construct about possible futures and the numbers that determine solvency.

A growing applied literature, much of it situated in emerging markets, had begun to address parts of this gap before the pandemic. Conceptual models have been proposed for data-driven executive decision systems in strategic financial planning (Lawal & Oduleye, 2019b), financial analytics as a driver of enterprise value (Lawal & Oduleye, 2018a), strategic accounting systems that strengthen transparency (Bola-Sadipe et al., 2019), reconciliation control and budget compliance in emerging-market organisations (Dogbatsey & Ebhojie, 2018; Dogbatsey et al., 2019), data-quality and single-source-of-truth reporting (Unamma et al., 2019a), and the use of natural language processing to extract value from unstructured financial records (Iziduh et al., 2020). Others have examined risk-based internal control and integrated

governance as sources of financial resilience (Akomolafe & Agu, 2019a; Akomolafe & Agu, 2019c). These contributions are valuable but typically address a single function, such as planning, audit, treasury or procurement, rather than the end-to-end process through which a firm converts signals of disruption into financial decisions.

1.3 Objectives and Research Questions

The purpose of this paper is to develop a conceptual framework that integrates risk assessment, scenario planning and financial sustainability analysis within a strategic financial modeling process aimed at enhancing business resilience. Specifically, the paper addresses three questions:

1. What are the essential components of a strategic financial modeling process capable of supporting decisions during severe economic disruption?
2. How should risk assessment, scenario planning and sustainability metrics be linked so that modeling outputs translate into timely management actions?
3. What theoretical mechanisms explain why such an integrated process should improve organisational resilience and financial sustainability?

1.4 Contributions and Structure

The paper makes three contributions. First, it synthesises dispersed literatures into a five-layer framework, the SFM-BR framework, that specifies the components, sequence and feedback loops of resilience-oriented financial modeling. Second, it grounds the framework in established theory and derives propositions that can guide future empirical research. Third, it offers practical tools, including a disruption risk taxonomy, a scenario archetype matrix, a trigger-based response playbook and a sustainability dashboard, together with a stylised numerical illustration.

The remainder of the paper is organised as follows. Section 2 describes the research method. Section 3 presents the results and discussion, comprising the literature synthesis, theoretical foundations, the conceptual model, research propositions, an illustrative application, discussion and implications. Section 4 concludes and sets out directions for future research.

2. RESEARCH METHOD

2.1 Research Design

This paper adopts a conceptual research design. Following Jaakkola (2020), it can be classified as a theory synthesis and model-building article: it integrates concepts from multiple literatures into a new framework

that specifies relationships among constructs. The approach is complemented by an integrative literature review in the sense described by Torraco (2005), which reviews, critiques and synthesises representative literature to generate new perspectives.

A conceptual design is appropriate for three reasons. First, the phenomenon of interest, the integration of modeling, scenario and risk practices during a systemic disruption, was still unfolding in 2020, so large-sample data on outcomes were not yet available. Second, the relevant knowledge is dispersed across disciplines that rarely cite one another, making synthesis the most productive first step. Third, a clearly specified framework with testable propositions provides the foundation on which later empirical studies can build.

2.2 Literature Identification and Selection

Sources were identified through searches of major academic databases and policy repositories using combinations of terms related to financial modeling, scenario planning, stress testing, liquidity, resilience, enterprise risk management and the COVID-19 crisis. Seminal works were included irrespective of date, while emphasis was placed on peer-reviewed studies and authoritative institutional publications. Early working papers from 2020 were included where they offered the first available evidence on the pandemic shock, recognising that their findings may be revised through peer review.

Three inclusion criteria were applied. Studies had to address at least one of the framework's core constructs (uncertainty and disruption, resilience, financial modeling and forecasting, scenario planning, liquidity and financing, risk governance, or operational and supply continuity); they had to offer a conceptual model, empirical evidence or an authoritative standard; and they had to be published no later than 2020, consistent with the paper's temporal scope. Applied studies from emerging economies, particularly Sub-Saharan Africa, were deliberately included because firms in these contexts face thinner capital markets, currency and commodity exposure, and infrastructure constraints that magnify the effects of disruption.

2.3 Synthesis and Model-Building Procedure

The synthesis proceeded in three stages. First, constructs and mechanisms were extracted from each literature stream. Second, these were mapped onto the stages of a decision process running from sensing to action and evaluation. Third, the mapped elements were organised into layers, and relationships among them were expressed as propositions. A stylised numerical illustration was then constructed to

demonstrate the internal logic of the framework. The illustration is hypothetical and is not intended as empirical validation.

Rigour was pursued through transparency about sources and assumptions, triangulation across literature streams, and explicit statement of the boundary conditions under which the framework is expected to hold. The propositions in Section 3.4 make the framework's claims falsifiable.

3. RESULTS AND DISCUSSION

This section presents the results of the integrative review and model-building process. It first synthesises the relevant literature and identifies the gaps it reveals, then sets out the theoretical foundations on which the framework rests. It next presents the conceptual model, derives research propositions and demonstrates the model through a stylised application, before discussing the findings and their implications.

3.1 Literature Synthesis

3.1.1 Economic Disruption, Risk and Uncertainty

A foundational distinction in the analysis of disruption is that between risk and uncertainty. Knight (1921) defined risk as a situation in which the probabilities of outcomes are measurable and uncertainty as one in which they are not. Most conventional financial models implicitly treat the future as a problem of risk: they assume stable relationships between variables and a distribution of outcomes that can be estimated from history. Systemic disruptions such as the 2008 global financial crisis and the 2020 pandemic are closer to Knightian uncertainty, in which historical relationships break down and the range of plausible outcomes is wide. Taleb (2007) characterised such events as rare, high-impact and explicable only in hindsight, and argued that reliance on models calibrated to normal conditions creates fragility.

Uncertainty itself has real economic effects. Bloom (2009) showed that uncertainty shocks cause firms to pause hiring and investment, producing sharp drops and rebounds in activity. Baker, Bloom and Davis (2016) developed a widely used index of economic policy uncertainty, and Baker et al. (2020) documented that pandemic-related uncertainty in early 2020 exceeded levels recorded during the global financial crisis. For financial modeling, the implication is that uncertainty is not merely a feature of the forecast error but a driver of the behaviour of customers, suppliers, lenders and competitors, and therefore of the cash flows being modelled.

3.1.2 Organisational Resilience

Resilience has been defined in management research as the capacity of an organisation to anticipate, absorb, adapt to and recover from disruptive events, and in some formulations to emerge stronger (Hamel & Välikangas, 2003; Linnenluecke, 2017). Williams et al. (2017) integrated the crisis management and resilience literatures, distinguishing resilience as a capability developed before adversity from the processes through which organisations respond during and after it. In supply chain research, Sheffi (2005) and Ponomarov and Holcomb (2009) emphasised redundancy and flexibility as sources of resilience, and Ivanov (2020) used simulation to show how the timing of facility closures and the speed of recovery shape the impact of epidemic outbreaks on supply chain performance.

A recurring theme is the tension between efficiency and resilience. Lean inventories, high operating leverage and debt-financed capital structures can raise returns in stable conditions but reduce the buffers available when conditions change. Resilience research has, however, been more explicit about operational and organisational buffers than about financial ones, and has rarely specified how resilience should be measured in financial terms.

Supply chain research has been especially active in translating resilience into practical constructs. Studies have shown how predictive analytics can improve demand forecasting accuracy and reduce inventory inefficiencies (Aifuwa et al., 2020), how ESG-integrated procurement links sourcing decisions to corporate responsibility (Okojie et al., 2020), and how agile supply chain digital transformation can embed IT risk and ISO compliance controls (Mbonu et al., 2020a). In regulated industries, traceability and chain-of-custody integrity (Aneke & Adesemoye, 2019), risk-based decision-making in manufacturing environments (Aneke & Adesemoye, 2020) and decision frameworks that reconcile safety with circular-economy targets (Okojie & Abioye, 2020) show how compliance requirements shape supply resilience. Data-driven performance monitoring in maritime logistics (Ijagbemi et al., 2019) illustrates the value of continuous operational visibility when trade flows are disrupted.

In energy and infrastructure settings, where supply interruptions translate directly into lost production, studies have developed supply chain risk management models for engineering, procurement and construction and gas processing projects (Agbabiaka et al., 2019), strategic procurement optimisation and inventory availability models to sustain plant uptime (Okonkwo et al., 2018a; Okonkwo et al., 2018b), and contract negotiation, vendor governance and contract design to secure reliable fuel and equipment supply (Asibor et al., 2019; Okonkwo et al., 2019). Force majeure provisions as a source of contractual

resilience (Uchechi et al., 2020), liability mitigation in high-value service contracts (Uchechi & Ominyi, 2019), port logistics and demurrage reduction (Okonkwo et al., 2020), and GIS-enabled ERP procurement (Ahiaeke Patrick et al., 2020) illustrate how operational buffers and contractual protections carry explicit financial costs and benefits. These financial trade-offs are precisely what a resilience-oriented financial model must capture.

3.1.3 Financial Modeling, Simulation and Stress Testing

Financial modeling in practice is anchored in integrated three-statement models that link the income statement, balance sheet and cash flow statement, together with discounted cash flow valuation (Damodaran, 2012). Hertz (1964) introduced Monte Carlo simulation to capital investment appraisal, arguing that single-point estimates conceal the distribution of possible outcomes. Glasserman (2004) and subsequent work extended simulation methods in finance. In risk management, Value at Risk and its corporate counterpart, Cash Flow at Risk, quantify the potential shortfall of a financial variable at a given confidence level over a given horizon (Jorion, 2007; RiskMetrics Group, 1999). Concerns about the inability of VaR to capture tail losses led to coherent risk measures such as Conditional Value at Risk (Artzner, Delbaen, Eber, & Heath, 1999; Rockafellar & Uryasev, 2000).

Stress testing, developed most extensively in banking supervision after 2008, evaluates the resilience of an institution to severe but plausible adverse scenarios (Basel Committee on Banking Supervision, 2018). Borio et al. (2014) cautioned that macro stress tests may fail to anticipate crises because they rely on models that do not capture non-linearities and feedback effects. Reverse stress testing, which begins from a failure outcome and works backwards to identify the conditions that would cause it, addresses part of this weakness. Despite their maturity in financial institutions, these techniques have been adopted unevenly by non-financial corporations, particularly small and medium-sized enterprises.

Within financial institutions, reviews of liquidity risk management and stress testing practices (Mensah et al., 2020), capital adequacy and risk-weighted asset optimisation (Mensah et al., 2019b), integrated ERM-based capital allocation (Mensah et al., 2019a) and data-driven risk evaluation in emerging-market institutions (Akomolafe & Agu, 2019b) document a mature toolkit. In corporate settings, applied work has extended predictive and data-driven methods to planning. Comparative reviews of predictive forecasting for operational resource allocation (Unamma et al., 2018b), profitability analysis using business intelligence tools (Akin-Oluyomi et al., 2020), predictive analytics for customer churn and lifecycle value (Oziri et al., 2020), geomarketing analytics for expansion decisions (Seyi-Lande et al.,

2020) and analytical models for measuring marketing return on investment (Sanni et al., 2020a) demonstrate how revenue drivers can be modelled explicitly. Regulatory scenario analysis that maps the sectoral impact of fiscal legislation (Akinola et al., 2020) shows how scenario logic can be applied to policy shocks.

Methodological choices within such models matter. Research comparing statistical distribution models for hazard prediction shows that the choice of distribution materially affects estimates of extreme outcomes (Ugwu et al., 2020), a point directly relevant to the selection of input distributions for Monte Carlo simulation. Multimodal forecasting approaches for long-term production estimates (Nwangwu et al., 2020), spatially explicit risk modeling in data-limited settings (Azeez & Badmus, 2018; Lamidi & Olamide, 2018) and hydrological modeling of climate-induced vulnerability trends (Badmus & Olamide, 2019) offer further examples of how uncertainty can be represented when historical data are sparse. Project scheduling optimisation using critical path analysis (Feboh et al., 2018) and analytical frameworks for improving the efficiency of public infrastructure delivery (Nwafor et al., 2019b) show how time and cost risk can be quantified in capital-intensive programmes. Few of these studies, however, situate their tools within a crisis decision process.

3.1.4 Scenario Planning

Scenario planning emerged at Royal Dutch Shell in the 1970s as a way of preparing managers for discontinuities that forecasts failed to predict (Wack, 1985). Schoemaker (1995) described scenario planning as a disciplined method for imagining possible futures and identifying the decisions that are robust across them. Courtney, Kirkland and Viguerie (1997) proposed that the appropriate strategic approach depends on the level of residual uncertainty, ranging from a clear enough future to true ambiguity. Bradfield, Wright, Burt, Cairns and van der Heijden (2005) traced the evolution of scenario techniques, and Wright and Goodwin (2009) argued that scenario thinking can counter cognitive biases such as overconfidence and framing that impair planning under low predictability.

A persistent criticism is that scenario planning often remains narrative and qualitative. Scenarios may be rich in story but thin in quantification, making it difficult to link them to liquidity, solvency or investment decisions. Conversely, purely quantitative sensitivity analysis varies one assumption at a time and fails to capture the correlated movements of variables that characterise real disruptions. Integration of the two traditions is therefore a central requirement of the framework proposed here.

3.1.5 Liquidity, Financial Flexibility and Corporate Survival

Corporate finance research provides strong theoretical and empirical support for the value of financial flexibility. Froot, Scharfstein and Stein (1993) showed that risk management creates value when external finance is costly, because it allows firms to fund valuable investments from internal resources. Myers and Majluf (1984) explained why firms prefer internal funds and why external finance becomes most expensive precisely when it is most needed. Opler et al. (1999) and Bates, Kahle and Stulz (2009) documented that firms hold cash as a precautionary buffer, particularly when cash flows are volatile. Campello et al. (2010) found that financially constrained firms cut investment, employment and technology spending more sharply during the 2008 crisis.

Evidence from 2020 reinforced these findings. Fahlenbrach et al. (2020) showed that firms with greater cash holdings experienced significantly smaller stock price declines when revenues stopped. Ramelli and Wagner (2020) found that investors penalised firms with high leverage and low cash. Acharya and Steffen (2020) documented a corporate dash for cash, with firms drawing down credit lines to secure liquidity, and Ding et al. (2020) linked pre-pandemic financial conditions and corporate characteristics to stock market resilience across countries. Gourinchas, Kalemli-Özcan, Penciakova and Sander (2020) estimated that, absent government support, small and medium-sized enterprise failure rates would rise substantially because of liquidity shortfalls. Together these studies indicate that liquidity runway and balance sheet flexibility are central determinants of survival under disruption.

The availability of external finance during disruption depends heavily on the health and practices of lenders. Research on emerging-market banking has reviewed credit decisioning and governance in corporate credit portfolios (Uzondu et al., 2020) and machine learning for credit risk and default prediction in retail and SME lending (Ashore-Onisemo et al., 2020). Studies of relationship banking performance, private banking partnership ecosystems and trade finance product design (Agboada et al., 2018b; Agboada et al., 2020; Ezeako et al., 2019), together with the adoption of web-based payment portals in Sub-Saharan Africa (Agyei et al., 2019), help explain why access to credit and payment channels varies across firms. At the corporate level, tax governance and cross-border compliance analytics (Lawal & Oduleye, 2018b), transfer pricing risk assessment (Lawal & Oduleye, 2019a), the standardisation of stamp duty policies to mitigate enterprise financial exposure (Uchechi, 2018) and multi-stakeholder governance in joint ventures (Eyetsemitan et al., 2020) show how tax, legal and partnership structures affect the cash available in a crisis.

3.1.6 Enterprise Risk Management

ERM frameworks seek to manage risks in an integrated, organisation-wide manner rather than in functional silos. The updated COSO (2017) framework explicitly links risk to strategy and performance, and ISO 31000 (ISO, 2018) provides principles and a process for risk management applicable to any organisation. Nocco and Stulz (2006) argued that ERM creates value by enabling firms to choose their total risk exposure in light of the costs of financial distress. Hoyt and Liebenberg (2011) reported a positive association between ERM adoption and firm value in the insurance sector. Kaplan and Mikes (2012) distinguished preventable risks, strategy risks and external risks, and argued that external risks, which include macroeconomic shocks and pandemics, require scenario-based and stress-testing approaches rather than rules-based control.

Applied work has extended these ideas, particularly in emerging-market organisations. Internal audit research has proposed technology-enabled risk assessment to enhance audit quality (Akomolafe & Agu, 2018) and examined audit precision as a foundation of financial accountability (Kinyanjui et al., 2019). IT governance frameworks such as COBIT and ITIL have been linked to regulatory compliance in insurance firms (Fadero et al., 2018), and security audit, risk-based cybersecurity assurance and legal and ethical risk modeling have been integrated into enterprise risk assessment (Dosunmu & Ogundele, 2019; Fadayomi et al., 2019; Mbonu et al., 2018; Mbonu et al., 2019a). Compliance research has addressed ethics and compliance training (Anichukwueze et al., 2020), consumer protection obligations in multinational marketing (Anichukwueze et al., 2019), procedural standardisation in dispute resolution (Uchechi et al., 2018) and digital complaint-resolution systems for accountability (Unamma et al., 2019b). Outside finance, predictive compliance monitoring and adaptive safety management systems (Adeyelu, 2018; Adeyelu, 2019) and internal QHSE audit systems (Obogo et al., 2020a) show how risk governance routines can be institutionalised. These works confirm the importance of integrating risk with strategy but rarely specify how risk information should flow into financial projections and contingency decisions.

3.1.7 Integrated Synthesis and Research Gaps

The review reveals four gaps that motivate this paper. First, scenario planning and quantitative financial modeling have developed largely in parallel, with limited integration. Second, quantitative risk tools are well established in financial institutions but less so in non-financial firms. Third, resilience research has emphasised organisational and operational capacities while underspecifying the financial mechanisms of resilience. Fourth, few frameworks explicitly connect model outputs to pre-defined management actions

through triggers and governance processes, so that modeling informs decisions in time to matter. Table 1 summarises the principal streams and their limitations.

Table 1. Summary of literature streams informing the framework

Literature stream	Core contribution	Key sources	Limitation addressed by SFM-BR
Uncertainty economics	Distinguishes risk from uncertainty; shows uncertainty shocks depress activity	Knight (1921); Bloom (2009); Baker et al. (2020)	Rarely translated into firm-level planning tools
Organisational resilience	Defines capacities to anticipate, absorb, adapt and recover	Hamel & Välikangas (2003); Linnenluecke (2017); Williams et al. (2017)	Financial mechanisms and metrics underspecified
Financial modeling and simulation	Integrated statements, DCF, Monte Carlo, CFaR	Hertz (1964); Jorion (2007); Damodaran (2012)	Often calibrated to normal conditions; weak link to strategy
Stress testing	Severe but plausible adverse scenarios; reverse stress tests	BCBS (2018); Borio et al. (2014)	Concentrated in banking; limited corporate adoption
Scenario planning	Multiple coherent futures; robust decisions	Wack (1985); Schoemaker (1995); Courtney et al. (1997)	Frequently qualitative and disconnected from cash flows
Liquidity and financial flexibility	Cash buffers and low leverage protect value and investment	Froot et al. (1993); Campello et al. (2010); Fahlenbrach et al. (2020)	Descriptive; limited guidance on planning processes
Enterprise risk management	Integrated, strategy-linked risk governance	COSO (2017); ISO (2018); Kaplan & Mikes (2012)	Process-oriented; limited quantitative specification

3.2 Theoretical Foundations

The framework draws on four complementary theoretical lenses, each of which explains a different aspect of how strategic financial modeling contributes to resilience.

3.2.1 Dynamic Capabilities Theory

Teece, Pisano and Shuen (1997) defined dynamic capabilities as the firm's ability to integrate, build and reconfigure internal and external competences to address rapidly changing environments. Teece (2007) later decomposed these capabilities into sensing, seizing and reconfiguring. Strategic financial modeling

can be understood as a micro-foundation of dynamic capabilities: environmental sensing identifies emerging threats, scenario-based modeling supports the evaluation of responses, and resource reallocation reconfigures the asset base. Under this view, the modeling process is not merely an analytical tool but an organisational routine that enables adaptation.

3.2.2 Real Options Theory

Real options theory treats managerial flexibility as a source of value under uncertainty (Dixit & Pindyck, 1994; Trigeorgis, 1996). Options to defer, expand, contract, switch or abandon investments are more valuable when uncertainty is high. During disruptions, preserving flexibility, for example by staging capital expenditure or negotiating variable cost structures, can be worth more than the returns sacrificed. The framework incorporates real options logic by treating contingency actions as options whose exercise is triggered by observed conditions.

3.2.3 Contingency Theory

Contingency theory holds that there is no single best way to organise and that effectiveness depends on the fit between organisational characteristics and environmental conditions (Donaldson, 2001). Applied to financial planning, it implies that the appropriate planning approach should vary with environmental volatility. Single-point budgets may suffice in stable conditions, whereas turbulent environments require rolling forecasts, multiple scenarios and shorter decision cycles (Hope & Fraser, 2003). The framework operationalises this by specifying how modeling cadence and scope should intensify as disruption signals strengthen.

3.2.4 Resource-Based View and the Pecking Order

The resource-based view attributes sustained performance to valuable, rare, inimitable and non-substitutable resources (Barney, 1991). Financial slack, in the form of liquidity and unused borrowing capacity, is a resource that enables firms to protect and redeploy their other strategic resources during disruption. The pecking order theory (Myers & Majluf, 1984) explains why this slack is especially valuable in crises: external finance becomes scarce and costly exactly when internal cash flows decline. Table 2 summarises how each lens informs the framework.

Table 2. Theoretical lenses and their role in the SFM-BR framework

Theory	Core premise	Implication for strategic financial modeling	Framework layer(s)
Dynamic capabilities	Firms must sense, seize and reconfigure to adapt	Modeling functions as an adaptive routine linking signals to resource reconfiguration	Layers 1, 4 and governance loop
Real options	Flexibility has value under uncertainty	Contingency actions are options exercised on triggers; flexibility should be valued explicitly	Layers 3 and 4
Contingency theory	Effective design fits the environment	Planning cadence and model scope should intensify with volatility	Governance loop
Resource-based view and pecking order	Slack resources protect strategic assets; external finance is costly in crises	Liquidity and borrowing capacity are strategic resources to be modelled and protected	Layers 2 and 5

3.3 Conceptual Model: The Strategic Financial Modeling for Business Resilience (SFM-BR) Framework

The SFM-BR framework conceives strategic financial modeling as a structured, iterative process that converts signals of disruption into quantified exposures, coherent scenarios, pre-agreed responses and monitored sustainability outcomes. Figure 1 depicts its architecture. Disruption signals feed a sequence of five layers. A governance, learning and continuous re-forecasting loop surrounds the layers, so that outcomes in Layer 5 inform renewed sensing in Layer 1. The intended outcome is business resilience, understood as the capacity to absorb shocks, adapt operations and finances, recover performance and, where possible, renew the business model.

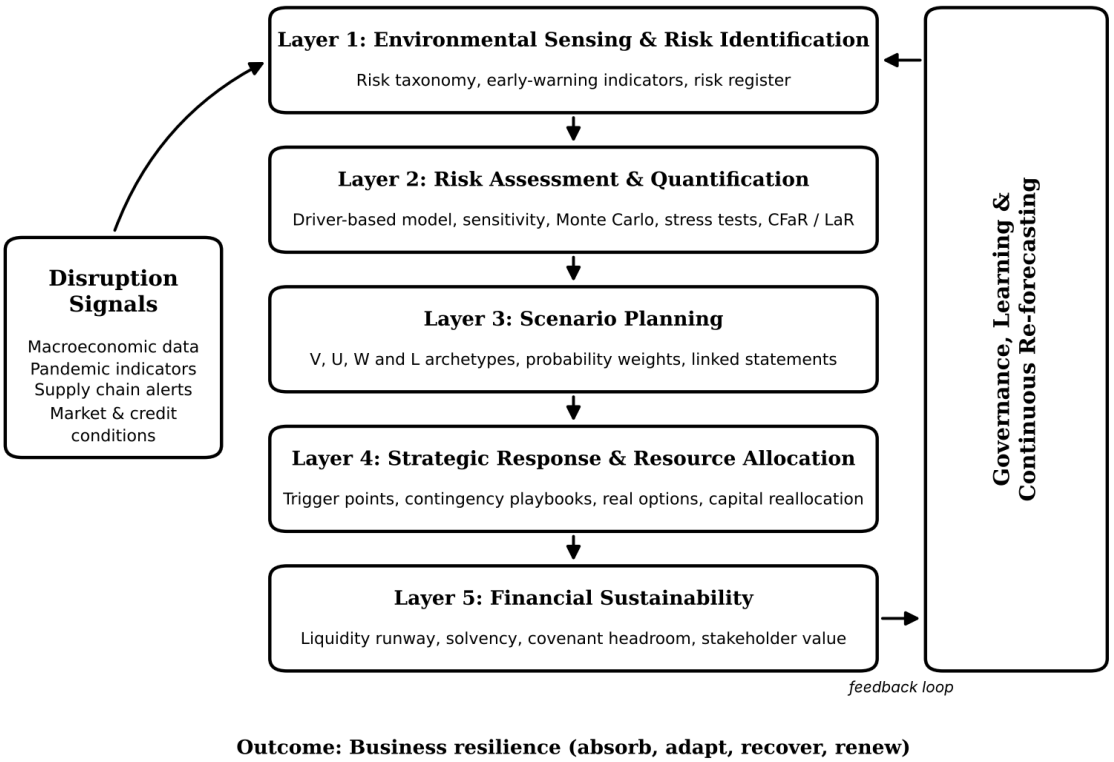

Figure 1. The Strategic Financial Modeling for Business Resilience (SFM-BR) framework

3.3.1 Layer 1: Environmental Sensing and Risk Identification

The first layer establishes the firm's awareness of the forces that could disrupt its cash flows. Its outputs are a structured risk taxonomy, a set of leading indicators, and a risk register linking each risk to the financial drivers it affects. The pandemic demonstrated that disruptions propagate through several channels simultaneously; a taxonomy that isolates demand risk from supply, financing and policy risks helps ensure that none is overlooked and that interactions among them are recognised. Table 3 presents a disruption risk taxonomy designed for this purpose.

Table 3. Disruption risk taxonomy and associated financial drivers

Risk category	Illustrative 2020 manifestations	Primary financial drivers affected	Leading indicators
Demand risk	Lockdowns, closure of venues, shift to online channels, loss of consumer confidence	Sales volume, price, product mix, channel mix	Mobility data, order books, consumer confidence, web traffic

Risk category	**Illustrative 2020 manifestations**	**Primary financial drivers affected**	**Leading indicators**
Supply and operational risk	Factory closures, border restrictions, input shortages, workforce absence	Cost of sales, capacity utilisation, inventory levels	Supplier status, lead times, freight rates, absenteeism
Liquidity and credit risk	Delayed customer payments, frozen credit markets, credit line drawdowns	Receivable days, available facilities, cost of debt	Credit spreads, ageing of receivables, bank appetite
Market and price risk	Commodity price collapse, currency depreciation, equity market volatility	Input costs, foreign currency debt, pension and investment values	Spot and futures prices, exchange rates, volatility indices
Counterparty risk	Insolvency of customers, suppliers or partners	Bad debt, replacement costs, revenue concentration	Counterparty credit ratings, payment behaviour
Policy and regulatory risk	Restrictions on activity, relief programmes, tax deferrals, payment moratoria	Operating capacity, subsidies, tax cash flows, debt service	Government announcements, policy trackers

Source: Author's synthesis drawing on Kaplan and Mikes (2012), Ivanov (2020) and Baker et al. (2020).

Two principles guide this layer. First, each risk should be mapped to specific model drivers so that a change in an indicator can be translated into a change in projected cash flows. Second, the firm should define a small number of leading indicators with explicit thresholds. These thresholds become the triggers that connect sensing to action in Layer 4.

The 2020 shift to remote working also elevated technology and cyber risk as a source of financial disruption, and the taxonomy should be extended accordingly where digital operations are material. Relevant studies address machine learning for cyber threat and anomaly detection (Okwesa et al., 2020), insider threat classification (Akeju et al., 2018), intrusion detection and prevention (Dosunmu & Ogundele, 2020), log analytics and automated incident response (Mbonu et al., 2019b; Okwesa et al., 2019), identity and access management in hybrid and federated environments (Mbonu et al., 2020; Oshoba et al., 2019), infrastructure-as-code governance (Mbonu et al., 2020b), blockchain-enabled audit trails for cloud configuration (Oshoba et al., 2020), privacy-centric security engineering (Okoruwa et al., 2020), predictive cloud resource scaling (Ahmed et al., 2020), operational technology security in electric utilities (Adegbite et al., 2020) and maturity models for standardising distributed IT support (Anyanwu, 2019). Each of these risks can interrupt revenue or impose unplanned costs and should therefore be mapped to model drivers.

Operational reliability is an important but often overlooked financial risk driver, because equipment failures and safety incidents can interrupt revenue and impose sudden costs at the moment liquidity is scarce. Research on reliability engineering and failure analysis (Gideon et al., 2019), failure mode and effects analysis and reliability-centred design (Ojeakhena et al., 2018a; Ojeakhena et al., 2018b), integrated hardware and software reliability (Asibor et al., 2020), predictive reliability assessment (Ogunnowo et al., 2020a), automated diagnostic logging and calibration (Ojeakhena et al., 2019a; Ojeakhena et al., 2019b), and the shift from reactive to predictive maintenance (Adaramola et al., 2018; Sunday et al., 2020) shows how such risks can be anticipated. In oil and gas, risk-based inspection, integrity management, reliability-centred and condition-based maintenance, corrosion management and non-destructive testing (Atta et al., 2020; Obetta & Ninduwezuor-Ehiobu, 2018; Obetta & Ninduwezuor-Ehiobu, 2019; Obetta et al., 2020; Obetta, 2018; Obetta, 2019; Obetta, 2020; Ogunnowo et al., 2020b) and risk-based process engineering (Asibor & Isong, 2019) link asset condition to production continuity. Occupational safety research, covering heat stress, drilling integrity, heavy lifting, contractor safety governance, hazard identification, safety culture and human error (Arumosoye & Obriki, 2018; Arumosoye & Obriki, 2020; Nwangwu et al., 2018; Obogo et al., 2019; Obogo et al., 2019a; Obogo et al., 2019b; Obogo et al., 2020b; Obogo et al., 2020c; Obriki & Arumosoye, 2018; Obriki & Arumosoye, 2020), indicates that safety failures are also a channel through which operational disruption becomes financial loss.

3.3.2 Layer 2: Risk Assessment and Quantification

The second layer quantifies exposures using a driver-based, integrated financial model. Instead of projecting line items as percentages of prior-year values, the model expresses revenues and costs as functions of operational drivers such as volumes, prices, conversion rates, headcount and payment terms. Revenue for product or segment i in period t, for example, can be represented as:

$$\text{Revenue}(i,t) = \text{Volume}(i,t) \times \text{Price}(i,t) \quad (1)$$

Costs are separated into variable and fixed components, which makes operating leverage explicit and allows the break-even level of activity to be computed directly. Free cash flow, the principal variable of interest for survival analysis, is then derived as:

$$\text{FCF}(t) = \text{EBITDA}(t) - \text{Taxes}(t) - \text{Capex}(t) - \Delta\text{NWC}(t) - \text{Interest}(t) \quad (2)$$

Three complementary techniques are then applied. **Sensitivity analysis** measures the response of key outputs to changes in individual drivers and identifies the drivers to which the firm is most exposed. **Monte**

Carlo simulation assigns probability distributions to uncertain drivers, including their correlations, and generates a distribution of outcomes from which measures such as Cash Flow at Risk can be estimated (Hertz, 1964; RiskMetrics Group, 1999). **Stress testing**, including reverse stress testing, evaluates outcomes under severe but plausible conditions and identifies the combinations of variables that would cause the firm to exhaust its liquidity or breach covenants (BCBS, 2018).

Machine learning and anomaly detection techniques can complement these methods by flagging unusual patterns before they appear in summary results. Applications include machine learning for credit default prediction (Ashore-Onisemo et al., 2020), anomaly detection in security and transaction data (Okwesa et al., 2020), data-driven methods for automation and process control (Adaramola et al., 2020), and artificial intelligence models for quantifying operational risk (Adeyelu, 2020). Because historical correlations may break down in a systemic crisis (Borio et al., 2014), simulation outputs must be interpreted cautiously and complemented by judgement-based scenarios. The most important single output of this layer is the liquidity runway, defined as:

$$\text{Runway (months)} = \frac{(\text{Cash} + \text{Undrawn committed facilities})}{\text{Net monthly cash burn}} \quad (3)$$

A related measure, Liquidity at Risk, can be defined as the minimum projected liquidity over the planning horizon at a specified confidence level. Where this value approaches zero, survival rather than profitability becomes the binding constraint on strategy.

3.3.3 Layer 3: Scenario Planning

The third layer integrates qualitative scenario thinking with the quantitative model. Scenarios are internally consistent descriptions of how the disruption might evolve, each translated into a full set of driver assumptions and run through the integrated three-statement model. This avoids the limitation of one-variable-at-a-time sensitivity analysis by ensuring that correlated variables move together, for example declining volumes accompanied by lengthening receivable days and tighter credit availability.

In 2020, analysts and policymakers commonly described possible recovery paths by the shape of the output curve. The framework adopts these shapes as scenario archetypes, presented in Table 4, while recognising that each firm must calibrate them to its own sector and markets.

Table 4. Scenario archetypes for economic disruption

Archetype	Narrative	Demand path	Working capital and financing conditions	Strategic emphasis
V-shaped	Sharp contraction followed by rapid rebound as restrictions ease	Severe but short decline; recovery within two to three quarters	Temporary strain; credit markets normalise quickly	Preserve capacity and talent for the rebound
U-shaped	Prolonged trough before gradual recovery	Depressed for several quarters; recovery over 12 to 24 months	Extended receivable days; selective lender appetite	Cost flexibility, liquidity extension, covenant management
W-shaped	Initial recovery interrupted by renewed restrictions or a second wave	Two contractions; volatile and uncertain timing	Repeated strain; reduced confidence among lenders and customers	Agility, staged decisions, avoid premature commitments
L-shaped	Structural break with lasting loss of demand or business model viability	Permanent step-down in revenue	Persistent constraints; refinancing risk elevated	Restructuring, portfolio change, business model renewal

Source: Author's synthesis.

Scenarios serve two distinct purposes. First, by assigning subjective probabilities, management can compute a probability-weighted expected outcome:

$$E[V] = \sum_s p_s \times V_s \text{ with } \sum_s p_s = 1 \quad (4)$$

Second, and more importantly in conditions of Knightian uncertainty, scenarios allow managers to identify robust strategies that perform acceptably across all plausible futures, and to recognise the scenario under which the firm would fail. Probability weights should therefore be treated as an aid to discussion rather than as precise estimates, and decisions should be tested against the most adverse plausible scenario as well as against the expected case (Wright & Goodwin, 2009).

3.3.4 Layer 4: Strategic Response and Resource Allocation

The fourth layer converts analytical outputs into action. Its central device is a trigger-based contingency playbook that specifies, before the need arises, which actions will be taken when particular indicators cross pre-defined thresholds. Pre-commitment reduces decision latency, mitigates the escalation of commitment and status quo biases, and ensures that the most time-sensitive actions, such as securing financing, are taken while options remain available. Table 5 illustrates a three-tier playbook.

Table 5. Illustrative trigger-based contingency playbook

Alert level	Illustrative triggers	Financial actions	Operational and strategic actions
Green (monitor)	Runway above 18 months; covenant headroom above 30 percent; revenue within 10 percent of plan	Monthly re-forecast; maintain liquidity buffer; review facility terms	Continue strategic investments; monitor leading indicators
Amber (prepare)	Runway 9 to 18 months; headroom 10 to 30 percent; revenue 10 to 25 percent below plan	Weekly 13-week cash forecast; draw or extend facilities; negotiate covenant relief early; tighten credit control	Freeze discretionary spending and hiring; defer non-critical capex; renegotiate supplier terms
Red (act)	Runway below 9 months; headroom below 10 percent; revenue more than 25 percent below plan	Daily cash management; seek new equity or debt; access government relief; dispose of non-core assets	Restructure cost base; exit unprofitable lines; reconfigure business model

Source: Author's illustration. Thresholds are indicative and must be calibrated to the firm's sector, cost structure and financing arrangements.

Response levers fall into six groups: cost flexibility (converting fixed to variable costs, temporary pay arrangements, renegotiated leases); working capital (inventory reduction, receivables collection, supplier terms); capital expenditure (deferral, staging or cancellation); financing (drawing facilities, raising new capital, covenant renegotiation, accessing public support schemes); pricing and revenue (channel shifts, product reconfiguration); and portfolio actions (divestment, closure or acquisition of distressed assets). Real options logic implies that actions which preserve future flexibility, such as staging rather than cancelling investments, should be preferred where their cost is modest relative to the value of the flexibility retained (Trigeorgis, 1996).

The applied literature provides practical detail on several of these levers. For working capital and procurement, strategic procurement optimisation and contract renegotiation offer quantifiable savings (Okonkwo et al., 2018a; Okonkwo et al., 2019), and profitability analysis and business intelligence applied to facility and property management help identify cost reductions (Akin-Oluyomi et al., 2020; Izuchukwu et al., 2020b). For energy costs, integrating solar power in small-scale manufacturing and optimising hybrid load distribution can reduce exposure to unreliable grid supply and fuel price volatility (Sunday & Omoegun, 2018; Sunday & Omoegun, 2019). Execution depends on organisational capability: standard operating procedures as change infrastructure and digital transformation in operations management (Agboada et al., 2018a; Agboada et al., 2019), together with workforce decisions on recruitment and

integration, supply chain talent development, competency frameworks and onboarding, technology talent development, digital inclusion and industry-academia collaboration (Akhigbe et al., 2020; Falemi et al., 2020; Nwangwu et al., 2019; Ukadike, 2018; Unamma et al., 2018a; Wikiri, 2019). Inclusive leadership pathways in African business (Ukadike & Ibeh, 2020) further shape whether cost actions preserve the human capital needed for recovery.

Resource allocation decisions in this layer must also balance survival against long-term competitiveness. Campello et al. (2010) showed that constrained firms cut investment in technology and employment during the 2008 crisis, potentially damaging future performance. The framework therefore requires that each response be evaluated not only for its immediate cash impact but also for its effect on strategic resources and post-crisis positioning.

3.3.5 Layer 5: Financial Sustainability

The fifth layer defines and monitors the outcomes by which resilience is judged. Financial sustainability is conceptualised here as the firm's ability to meet its obligations through the disruption (short-term survival), maintain a viable capital structure (medium-term solvency) and continue to generate returns above its cost of capital (long-term value creation), while maintaining the confidence of key stakeholders. Table 6 presents a sustainability dashboard organised around these dimensions.

Table 6. Financial sustainability dashboard

Dimension	Metric	Definition	Resilience interpretation
Liquidity	Liquidity runway	(Cash + undrawn committed facilities) ÷ net monthly burn	Time available to adapt before external funding is required
Liquidity	Quick ratio	(Current assets − inventory) ÷ current liabilities	Capacity to meet near-term obligations from liquid assets
Solvency	Net debt to EBITDA	(Debt − cash) ÷ EBITDA	Leverage relative to earnings; common covenant measure
Solvency	Interest coverage	EBIT ÷ interest expense	Ability to service debt from operations
Solvency	Covenant headroom	(Covenant limit − actual) ÷ covenant limit	Distance from technical default
Operating resilience	Break-even revenue	Fixed costs ÷ contribution margin ratio	Revenue decline the firm can absorb before losses

Dimension	Metric	Definition	Resilience interpretation
Operating resilience	Degree of operating leverage	Contribution margin ÷ EBIT	Sensitivity of profit to changes in revenue
Distress risk	Altman Z-score	Weighted combination of liquidity, profitability, leverage and activity ratios	Composite early indicator of insolvency risk (Altman, 1968)
Long-term value	ROIC relative to WACC	Return on invested capital minus weighted average cost of capital	Whether recovery restores value creation

Source: Author's synthesis drawing on Altman (1968) and Damodaran (2012).

Sustainability in this framework also extends to stakeholder relationships. Decisions that preserve liquidity at the cost of supplier insolvency, employee welfare or customer trust may weaken the ecosystem on which recovery depends. The dashboard should therefore be complemented by qualitative assessment of stakeholder impacts, consistent with the integration of strategy and performance emphasised in COSO (2017).

Sector studies show how the meaning of financial sustainability varies with context. In healthcare, it encompasses insurance financing and provider payment design, the translation of innovation into patient outcomes, pharmacy-led access models, capital equipment and infrastructure financing, and analytics-based assessment of health needs (Aminu-Ibrahim et al., 2018; Aminu-Ibrahim et al., 2019; Atakpa & Abolaji, 2020; Ilodigwe & Adesemoye, 2019a; Ilodigwe & Adesemoye, 2019b; Ilodigwe & Adesemoye, 2020; Okoli et al., 2020), supported by workforce competencies suited to diverse health systems (Peteranaba et al., 2019). In energy, it involves renewable integration strategy, smart microgrids for rural electrification, affordability-performance trade-offs in solar microgrids, hydrogen integration, distribution network design and flare-gas recovery (Adeniji et al., 2020; Asibor & Isong, 2020; Komi & Adeniji, 2020; Nnaji et al., 2019; Shittu et al., 2019; Yeboah & Ike, 2020). Environmental and social dimensions enter through revenue opportunities in waste management (Nwude et al., 2019b), urban housing affordability (Gil-Ozoudeh et al., 2018), flood resilience in African cities (Nwafor et al., 2019a) and digital building compliance systems (Izuchukwu et al., 2020a).

3.3.6 Governance, Learning and Continuous Re-forecasting

The governance loop ensures that the framework operates as a living process rather than a one-off exercise. Consistent with contingency theory and the Beyond Budgeting critique of fixed annual plans (Hope & Fraser, 2003), the framework replaces or supplements the annual budget with rolling forecasts whose

frequency increases with the alert level. A rolling 13-week cash flow forecast, updated weekly in amber and red conditions, is the operational core of liquidity governance during disruptions.

Four governance elements are specified. First, clear ownership: a cross-functional crisis finance team, with board oversight, owns the model, the scenarios and the playbook. Second, model risk management: assumptions are documented, versions controlled and outputs reviewed independently, in line with principles developed for financial institutions (Board of Governors of the Federal Reserve System, 2011). Third, communication: scenario outputs are shared with lenders, investors and employees in a manner that builds credibility. Fourth, learning: after each cycle, forecast errors are analysed, scenarios are refined and triggers recalibrated, so that the organisation's sensing and response capability improves over time.

Learning routines from safety management offer a useful analogy for the financial learning loop. Studies of near-miss and hazard observation data and of management safety walkthroughs show that organisations improve when they systematically analyse weak signals and small failures rather than waiting for major incidents (Arumosoye & Obriki, 2019; Obriki & Arumosoye, 2019). Applied to financial modeling, the analysis of forecast errors, missed triggers and near breaches of covenants or liquidity thresholds can serve the same purpose.

3.4 Research Propositions

The framework implies a set of relationships that can be tested empirically. The following propositions are offered as a basis for future research.

Proposition 1. Firms that employ driver-based, integrated financial models with multiple quantified scenarios will detect liquidity shortfalls earlier during economic disruptions than firms relying on single-point budgets.

Proposition 2. The positive effect of pre-crisis liquidity on firm survival during disruption is strengthened when the firm has pre-defined, trigger-based contingency plans linked to its financial model.

Proposition 3. The integration of qualitative scenario narratives with quantitative financial modeling is positively associated with the timeliness and quality of strategic resource reallocation decisions during disruption.

Proposition 4. Increasing re-forecasting frequency in response to rising environmental volatility is positively associated with forecast accuracy and with the speed of management response.

Proposition 5. Firms that evaluate crisis responses for both immediate cash impact and long-term strategic effect will experience stronger post-crisis performance than firms that prioritise cash preservation alone.

Proposition 6. The relationship between strategic financial modeling capability and resilience is moderated by firm size and access to external finance, with the marginal benefit greatest for financially constrained firms.

3.5 Illustrative Application

To demonstrate the internal logic of the framework, consider a stylised mid-sized manufacturing firm, referred to as Firm M. The figures are hypothetical and simplified for exposition. Before the disruption, Firm M generates annual revenue of USD 120 million with variable costs equal to 55 percent of revenue and fixed operating costs of USD 36 million, producing EBITDA of USD 18 million (a 15 percent margin). It holds USD 18 million in cash, has an undrawn committed revolving credit facility of USD 10 million and gross debt of USD 30 million, with annual interest of USD 2 million and maintenance capital expenditure of USD 6 million. Its loan agreement contains a covenant limiting net debt to EBITDA to 3.5 times.

Applying Layer 3, management develops four scenarios for the next twelve months, calibrated to the archetypes in Table 4, and assigns subjective probabilities. Working capital absorption reflects lengthening customer payment periods in the more severe scenarios. Taxes are ignored for simplicity. The results are shown in Table 7.

Table 7. Scenario outputs for Firm M over a twelve-month horizon (USD million)

Item	V-shaped	U-shaped	W-shaped	L-shaped
Probability	0.25	0.40	0.20	0.15
Revenue change	−10%	−25%	−30%	−45%
Revenue	108.0	90.0	84.0	66.0
Contribution (45% of revenue)	48.6	40.5	37.8	29.7
Fixed costs	36.0	36.0	36.0	36.0
EBITDA	12.6	4.5	1.8	(6.3)
Capex and interest	8.0	8.0	8.0	8.0
Working capital absorption	0.0	2.0	3.0	4.0
Free cash flow	4.6	(5.5)	(9.2)	(18.3)

Item	V-shaped	U-shaped	W-shaped	L-shaped
Ending cash	22.6	12.5	8.8	(0.3)
Ending liquidity (cash + facility)	32.6	22.5	18.8	9.7
Runway on opening liquidity (months)	Cash generative	61	37	18
Net debt to EBITDA (limit 3.5x)	0.6x	3.9x (breach)	11.8x (breach)	n.m. (breach)

Source: Author's illustration. Figures in parentheses are negative. Runway is opening liquidity of USD 28 million divided by average monthly cash burn. n.m. = not meaningful because EBITDA is negative.

Three insights emerge. First, the probability-weighted expected EBITDA is approximately USD 4.4 million and expected ending cash approximately USD 12.4 million. Taken alone, these figures suggest a manageable situation. The scenario view, however, reveals that under the L-shaped outcome the firm exhausts its cash and depends entirely on its revolving facility. This illustrates why expected values are an insufficient basis for decisions under deep uncertainty.

Second, liquidity and covenant compliance diverge. In the U-shaped scenario, which carries the highest probability, the firm retains ample liquidity, with an implied runway of about five years, yet breaches its leverage covenant because EBITDA falls faster than net debt. A breach could allow lenders to withdraw the facility on which the firm's runway partly depends. A model that tracked only cash would miss this interaction. Under the framework, the projected breach would place the firm in the amber zone and trigger early negotiation of covenant relief, an action that is far more likely to succeed before a breach occurs than after it.

Third, pre-defined responses materially change outcomes in the severe scenario. Suppose that in the L-shaped case the red-zone playbook reduces fixed costs by 15 percent (USD 5.4 million), defers half of capital expenditure (USD 3.0 million) and recovers USD 2.0 million of working capital through tighter credit control. Free cash flow improves by USD 10.4 million, ending cash rises from negative USD 0.3 million to USD 10.1 million, and ending liquidity doubles from USD 9.7 million to USD 20.1 million. The value of the framework lies not in predicting which scenario will occur but in ensuring that these actions are identified, quantified and agreed in advance, so that they can be executed quickly if leading indicators point toward the L-shaped path.

3.6 Discussion

3.6.1 Interpretation of the Framework

The framework responds to the central problem identified in the introduction: the disconnect between the narratives executives construct about uncertain futures and the numbers that determine solvency. By requiring that every scenario be expressed through a driver-based, integrated three-statement model, the framework turns qualitative judgement into quantified exposures without discarding the challenge to assumptions that scenario thinking provides (Schoemaker, 1995; Wright & Goodwin, 2009). By linking those exposures to pre-agreed triggers and responses, it addresses the decision latency that crisis management research identifies as a source of failure (Williams et al., 2017).

The illustrative application highlights two findings that are easily missed in conventional planning. First, expected values computed across scenarios can conceal survival-threatening outcomes, consistent with arguments that models calibrated to normal conditions create fragility (Taleb, 2007). Second, liquidity adequacy and covenant compliance can diverge, so a firm that monitors only cash may lose access to the facilities on which its runway depends. This reinforces corporate finance evidence that financial flexibility, not profitability alone, determined firm outcomes in 2020 (Fahlenbrach et al., 2020; Acharya & Steffen, 2020).

The framework is also consistent with applied evidence from emerging economies, where business continuity preparedness, procurement resilience and liquidity stress testing distinguished organisations that sustained operations through the pandemic (Babayemi et al., 2020; Fadero et al., 2020; Mensah et al., 2020). In such settings, thinner capital markets and currency and commodity exposure mean that the liquidity and covenant mechanisms emphasised by the framework are likely to bind earlier and more severely than in developed markets.

3.6.2 Theoretical Contributions

The framework contributes to resilience theory by specifying financial mechanisms through which resilience is built and measured. It positions liquidity runway, covenant headroom and operating leverage as quantifiable indicators of absorptive capacity, and trigger-based playbooks as mechanisms of adaptive capacity. It contributes to the dynamic capabilities literature by identifying strategic financial modeling as a concrete organisational routine underpinning sensing, seizing and reconfiguring. It also extends the scenario planning literature by showing how narrative scenarios can be operationalised through integrated financial statements without losing their value as tools for challenging assumptions.

3.7 Implications

3.7.1 Managerial Implications

For managers and boards, the framework suggests several practical priorities:

- Rebuild planning models around operational drivers and separate fixed from variable costs, so that the effect of a disruption can be traced directly to cash.
- Maintain a small set of coherent scenarios, including a severe but plausible downside, and update them as conditions evolve rather than relying on a single forecast.
- Monitor covenant headroom alongside liquidity, and engage lenders early when projections indicate a potential breach.
- Agree trigger-based contingency actions in advance, with clear ownership and thresholds, to shorten decision time during a crisis.
- Evaluate cost and investment cuts for their long-term strategic effect as well as their immediate cash benefit.
- Treat financial slack as a strategic resource and reconsider the trade-off between efficiency and resilience in capital structure and working capital policies.

3.7.2 Implications for Lenders, Investors and Policymakers

Lenders and investors can use the framework to evaluate borrowers' and investees' preparedness. A firm that can demonstrate scenario-based liquidity analysis and credible contingency plans presents a lower risk of disorderly distress. For policymakers, the framework highlights that liquidity shortfalls, rather than insolvency in the economic sense, may cause otherwise viable firms to fail during temporary shocks (Gourinchas et al., 2020). Support measures such as guaranteed lending, tax deferrals and payment moratoria are most effective when firms can quantify their needs and the conditions under which they would recover. Capacity-building in financial modeling, particularly for small and medium-sized enterprises and firms in emerging and commodity-dependent economies where external finance is scarcer and currency and commodity shocks compound the disruption, could therefore complement direct financial support. Evidence on access to agribusiness finance and entrepreneurial competencies in rural and youth enterprises supports this view (Michael & Ogunsola, 2019a; Michael & Ogunsola, 2019b), as does research on product, brand and communication strategies for firms in emerging markets (Agyei et al., 2018; Sanni et al., 2020b; Sanni et al., 2020c).

3.7.3 Regulatory Implications

Regulatory design matters as well. Legal barriers to import and export participation affect how quickly small firms can redirect sales during disruptions (Jones & Ominyi, 2020). Regulatory clearance and post-merger compliance integration influence the speed at which distressed assets can be restructured or acquired (Ominyi & Anichukwueze, 2020; Ominyi, 2020), while statutory licensing, public bidding, regulatory risk assessment and policy advocacy shape the risk profile of energy firms (Ominyi et al., 2020; Uchechi & Ominyi, 2020; Uchechi et al., 2019). Policymakers seeking to strengthen resilience should therefore consider how regulatory processes affect the financial flexibility on which firms depend during crises.

4. CONCLUSION

4.1 Concluding Remarks

The economic disruption of 2020 demonstrated that business resilience depends not only on operational flexibility and organisational culture but also on the ability to understand, quantify and act upon financial exposures under deep uncertainty. Conventional planning approaches, built for stable environments, proved inadequate for this task. This paper has proposed the SFM-BR framework, which integrates environmental sensing, risk quantification, scenario planning, trigger-based strategic response and financial sustainability monitoring within a governance loop of continuous re-forecasting and learning.

Grounded in dynamic capabilities, real options, contingency and resource-based theories, the framework explains why such integration should enhance resilience: it shortens the time between signal and action, makes the value of flexibility explicit, aligns planning intensity with environmental volatility and protects the financial slack that enables firms to sustain their strategic resources. The illustrative application shows that integrated modeling can reveal risks that single-point forecasts or expected values conceal, such as the divergence between liquidity and covenant compliance, and that pre-agreed responses can materially improve survival prospects in severe scenarios. The framework offers researchers a set of testable propositions and offers practitioners a structured approach to building organisations that can withstand, adapt to and recover from the disruptions that are likely to recur.

4.2 Future Research

The framework and its propositions suggest a research agenda with several strands:

- **Empirical testing of the propositions.** Survey and archival studies could test Propositions 1 to 6 by comparing planning practices before 2020 with liquidity, covenant and survival outcomes during and after the disruption.
- **Longitudinal and case study research.** In-depth case studies could trace how firms translated scenarios into actions in 2020, and longitudinal designs could assess whether resilience gains persisted into the recovery.
- **Contextual moderators.** Research could examine how firm size, industry, ownership and institutional context, including emerging and commodity-dependent economies, moderate the relationship between modeling capability and resilience.
- **Tools for small enterprises.** Simplified, low-cost versions of the framework, such as a rolling 13-week cash model with three scenarios and a short trigger list, should be developed and evaluated for small and medium-sized enterprises.
- **Advanced analytics.** Studies could explore how machine learning, anomaly detection and real-time data could strengthen the sensing and quantification layers while preserving the judgement that deep uncertainty demands.
- **Non-financial dimensions.** Future work should integrate operational, human, technological and environmental dimensions of resilience with the financial mechanisms emphasised here.
